# Introduction

## Induced acceleration (IA) analyses

- Quantifies contributions of individual forces and moments to accelerations, reaction forces, and powers produced during a task
- Decomposition based on instantaneous effect of applying individual forces to a dynamic model
- Because of dynamic coupling, contributions often non-intuitive

# IA analyses of locomotion

- Analysis has been used to assess muscle/joint moment function during locomotion
  - Vertical/forward acceleration of trunk or center of mass
    - Kepple, 1997; Neptune, 2001, 2003; Riley, 2001; Anderson, 2003; Zajac, 2003;
  - Mechanical powers of trunk and legs
    - Neptune, 2001, 2003; Zajac, 2003
- Can infer muscle coordination principles and potentially assist diagnosis of gait pathologies

## IA contributions physically well-defined?

- Results and interpretations have differed between studies -> Controversy
- Are contributions well-defined or do they depend very much on formulation of model?
- In this study, assessment made possible by analyses of a simple, theoretical locomotor task using different models

# Methods

# Theoretical locomotor task

- Based on a planar, rigid body simulation
- Four segments – Trunk, thigh, shank, and foot of supporting leg
- Joint moments prescribed to maintain configuration of body as it rolled forward over pin joint

# IA analyses using 4 models

Model 1  
Hip, Knee, Ankle DOFs

Model 2  
Hip, Knee DOFs

Model 3  
Hip DOF

Model 4  
Single Segment

- Contributions of joint moments and gravity and centrifugal forces to
  - Vertical/ Horizontal GRF
  - Mechanical powers of trunk and leg
- Models 1 through 4
  - Represented progressively fewer degrees of freedom
  - All described simulated task dynamics

# Results

# Vertical GRF contributed by each moment/force differed between models

Example:

Contributed Vertical GRF  
(% Body Weight)

— Model 1: Hip, Knee, Ankle DOFs  
— Model 2: Hip, Knee DOFs

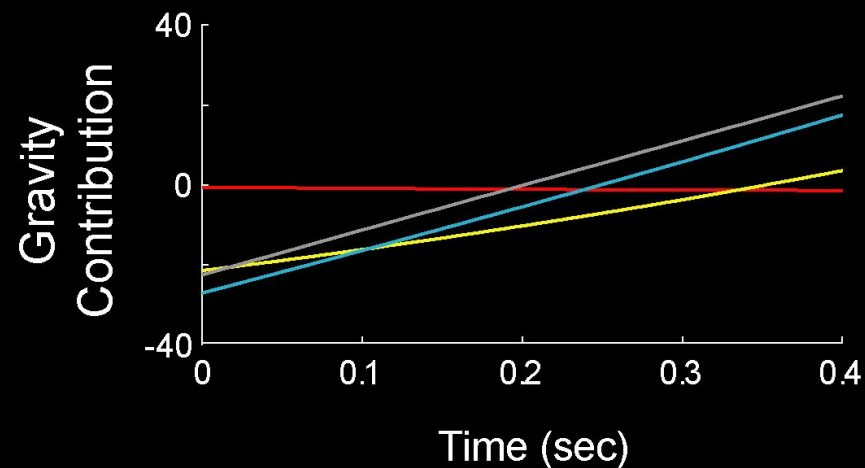

# Horizontal GRF contributed by each moment/force differed between models

Example:

Horizontal GRF  
(% Body Weight)

- Model 1: Hip, Knee, Ankle DOFs
- Model 2: Hip, Knee DOFs
- Model 3: Hip DOF
- Model 4: Single Segment

# Trunk and leg powers contributed by each moment/force differed between models

Example:

Contributed Trunk Power  
(Watts)

— Model 1: Hip, Knee, Ankle DOFs  
— Model 2: Hip, Knee DOFs  
— Model 3: Hip DOF

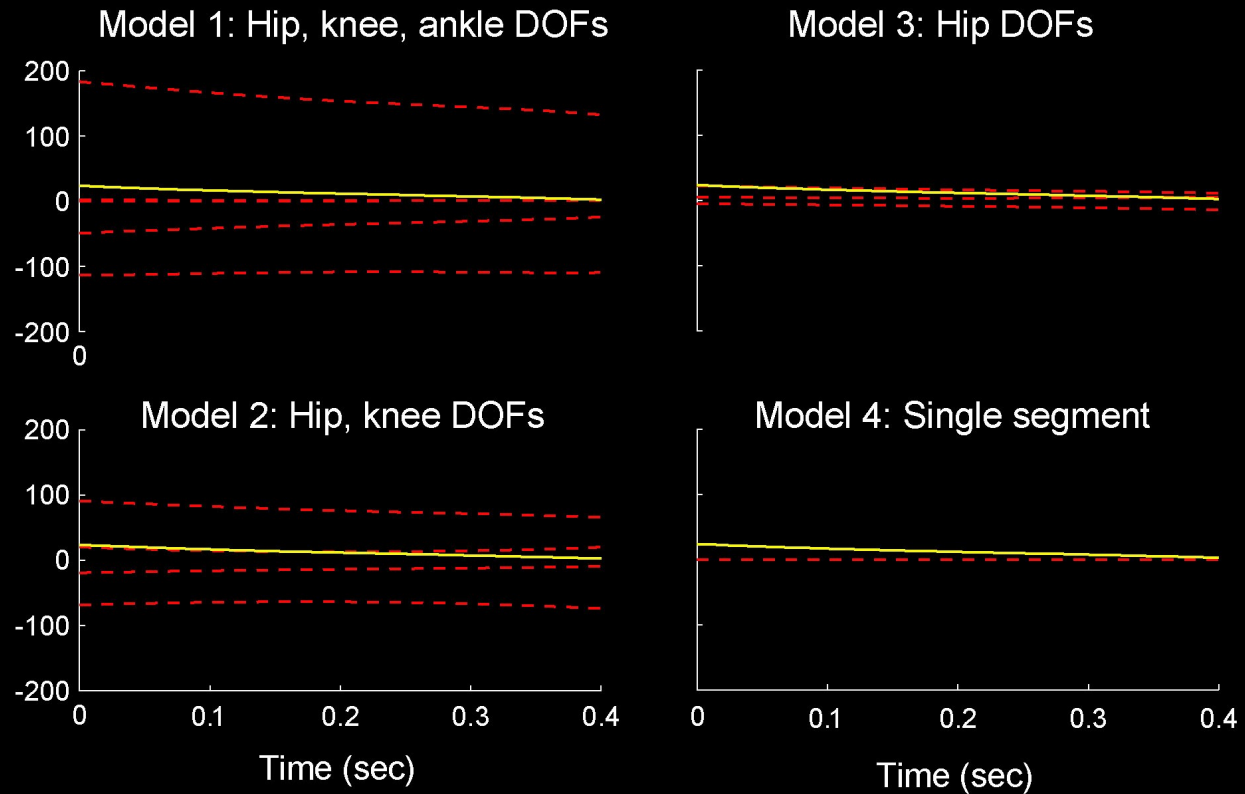

# Total contributions -> Identical for all models!

Example:

Contributed Leg power  
(Watts)

-- Individual contributions  
— Total contribution

# Discussion

## IA contributions to the dynamics of a task are not physically well-defined

- Even though all models described simulated task dynamics, decomposition of GRF and powers differed between models
- Application of analysis in assessment of muscle and joint moment function during locomotion should be critically reevaluated

## Remaining question: Contributions for any particular model meaningful?

- Ex., Do contributions represent moment's role in providing “support”, “forward progression”, etc.?
- Analyses suggests, maybe not.
  - Chen, 2005 (Gait & Posture, in press)
- Advantage of analyzing a simple task -> Results can be evaluated
- You have to understand the analysis, before it's applied to a complex task!

Thank you
